Sample Database Exam Questions and Detailed Answers

To illustrate the typical questions and how to approach them, here are some sample questions with comprehensive answers.

Question 1: What is a Database? Explain its types.

Answer: A database is an organized collection of data that is stored electronically on a computer system. It allows efficient storage, retrieval, management, and updating of data. Databases are designed to handle large volumes of data systematically, ensuring data integrity, security, and accessibility. Types of Databases: - Hierarchical Database: Data is organized in a tree-like structure with parent-child relationships. Example: IBM Information Management System (IMS). - Network Database: Data is represented as records connected through links, supporting multiple relationships. Example: Integrated Data Store (IDS). - Relational Database: Data is stored in tables (relations), with relationships established via foreign keys. Example: MySQL, Oracle, SQL Server. - Object-Oriented Database: Data is stored as objects, similar to object-oriented programming paradigms. - NoSQL Databases: Designed for unstructured or semi-structured data, supporting flexible schemas (e.g., MongoDB, Cassandra).

Question 2: Explain the concept of normalization and its levels.

Answer: Normalization is a systematic process of organizing data in a database to reduce redundancy and dependency. The goal is to ensure data integrity and optimize storage. Levels of Normalization: 1. First Normal Form (1NF): - Eliminates duplicate columns. - Ensures each field contains atomic (indivisible) values. - Example: A table with multiple phone numbers in one field violates 1NF. 2. Second Normal Form (2NF): - Achieves 1NF. - Removes partial dependency; non-primary key attributes depend fully on the primary key. - Example: In a table with composite primary key, attributes depend on both parts. 3. Third Normal Form (3NF): - Achieves 2NF. - Removes transitive dependency; non-primary attributes depend only on the primary key. - Example: Avoid storing customer name and customer address in the same table if address depends on customer ID. 4. Boyce-Codd Normal Form (BCNF): - A stronger version of 3NF. - Ensures every determinant is a candidate key. Higher normal forms exist but are less common in practical applications.

Question 3: Write an SQL query to fetch the names of customers who

placed orders worth more than $1000.

Answer: SELECT customer_name FROM customers c JOIN orders o ON c.customer_id = o.customer_id WHERE o.order_total > 1000; Explanation: - The query joins the `customers` and `orders` tables on the `customer_id`. - It filters orders where the total amount exceeds $1000. - It retrieves the names of the customers who meet this criterion.

Question 4: What are the ACID properties in database transactions? Why are they important?

Answer: ACID is an acronym representing the key properties that ensure reliable processing of database transactions: - Atomicity: Guarantees that all operations within a transaction are completed successfully or none are applied. Ensures consistency even in case of failures. - Consistency: Ensures that a transaction brings the database from one valid state to another, maintaining data integrity rules. - Isolation: Transactions are executed independently without interference, preventing concurrent transaction conflicts. - Durability: Once a transaction is committed, its effects are permanent, even in case of system failures. Importance: These properties are essential for maintaining data accuracy, reliability, and integrity, especially in environments with concurrent users and potential failures.

Question 5: Describe the process of designing an ER diagram for a university database system.

Answer: Designing an Entity-Relationship (ER) diagram involves several steps: 1. Identify Entities: Determine the main objects or concepts, such as Students, Courses, Professors, Departments. 2. Define Relationships: Establish how entities are related. For example, Students enroll in Courses, Professors teach Courses. 3. Determine Attributes: Specify properties for each entity (e.g., Student: StudentID, Name, Major). 4. Establish Keys: Identify primary keys for entities and foreign keys for relationships. 5. Create ER Diagram: - Use rectangles for entities. - Use diamonds for relationships. - Connect entities and relationships with lines. - Add attributes with ovals connected to respective entities or relationships. Example: - Entities: Student, Course, Professor - Relationships: - Enrolled (between Student and Course) - Teaches (between Professor and Course) - Attributes: - Student: StudentID (PK), Name, Major - Course: CourseID (PK), CourseName, Credits - Professor: ProfessorID (PK), Name, Department This diagram serves as a blueprint for creating relational tables.
